Summary

Background

Despite debriefing being found to be the most important element in providing effective learning in simulation-based medical education reviews, there are only a few examples in the literature to help guide a debriefer. The diamond debriefing method is based on the description, analysis and application technique, along with aspects of advocacy enquiry and debriefing with good judgement. It is specifically designed to allow an exploration of the non-technical aspects of a simulated scenario.

Context

The debrief diamond, a structured visual reminder of the debrief process, was developed through teaching simulation debriefing to hundreds of faculty over several years. The diamond shape visually represents the idealised process of a debrief: opening out a facilitated discussion about the scenario,
before bringing the learning back into sharp focus with specific learning points.

Innovation

The diamond is a two-sided prompt sheet: the first contains the scaffold with a series of specifically constructed questions for each phase of the debrief; the second lays out the theory behind the questions and the process.

Implication

The diamond encourages a standardised approach to high-quality debriefing on non-technical skills. Feedback from learners and from debriefing faculty has indicated that the diamond is useful and valuable as a debriefing tool, benefiting both participants and faculty members. It can be used by junior and senior faculty members debriefing in pairs, allowing junior faculty to conduct the description phase while more experienced faculty lead the later and more challenging phases. The diamond gives an easy but pedagogically sound structure to follow and specific prompts to use in the moment.

MAIN ARTICLE:

Background

High-fidelity simulation utilizes life-size mannequins in actual or re-created clinical environments to provide a clinical training experience without posing any risk to real patients. It can be used for all types of health care
professional at any stage, pre- or post-qualification. Though it is used for many types of training, it is ideally suited for the teaching of non-technical skills such as team working, prioritising and leadership, and it provides a unique opportunity for interprofessional education (1).

Simulation-based medical education reviews consistently find debriefing to be the most important element in providing effective learning (2, 3). A commonly-used definition of debriefing is a “facilitated or guided reflection in the cycle of experiential learning” that occurs after a learning event (4). Despite the recognized importance of debriefing, there are only a few examples in the literature to help guide a debriefer (5-7). Leading experts in the field have called for work to “define explicit models of debriefing” (8). In response to this, the authors set out to develop a clear and simple visual aid to debriefing of clinical events, be they simulated or real.

The debriefing method upon which the diamond is based has at its core the technique of description, analysis and application (6) technique, along with aspects of advocacy-inquiry approach and of debriefing with good judgement (5).

**Context**

The debrief diamond was developed through the work of the authors at the simulation centre of a large academic health sciences centre and hospital system in the UK. The diamond was developed over time based on the personal debriefing episodes of the authors, our work training over 500
novices on courses and in practice by ‘debriefing the brief’. These experiences suggested that a structured visual reminder would benefit faculty and participants.

We observed that faculty members often start a debrief confidently, but can find it difficult to structure a discussion around non-technical skills. They frequently allowed technical skills to dominate the discussion, used closed questions and reverted to didactic instructional approaches or traditional feedback tools such as Pendleton’s rules (9).

In order to address this, we developed an initial debriefing aid for new simulation faculty that listed specific questions, prompts and reminders, used in the description, analysis, application debriefing model. This was integrated into our faculty debriefing courses and used during all our simulation courses. We observed an increase in the quality of facilitation and a decrease in didactic teaching. Candidates talked more and shared more clinical stories that illustrated non-technical skills. However, facilitators were still rarely able to develop specific, personalised learning points for learners to take away.

Recognising these issues, we believed the debrief sheet needed further evolution. This was when two ideas intersected:

1. Integrating a cognitive scaffold of question prompts separated by clearly signposted transitions between phases.
2. Using the diamond shape to visually represent the idealised process of a debrief: opening out a facilitated discussion about the scenario, before bringing the learning back into sharp focus with specific learning points.

**Innovation**

The diamond was developed as a double-sided page. The first side contains the scaffold with a series of specifically constructed questions for each phase of the description, analysis, application debrief. The second side lays out the theory behind the questions and the process enabling the debriefing faculty to quickly remind themselves of the learning environment they are trying to create and how this can be achieved.

While the question prompts may seem didactic and inflexible, this is purposeful and suits the aim of a cognitive scaffold. It enables new faculty to practice their debriefing skills, initially with close adherence to the prompts. When the faculty member is more experienced, the model can act as a guide rather than a script. Experienced debriefing faculty have found that retaining the specific components, such as transitions (e.g. *this scenario was designed to show...*) serves to signpost the process for both learners and faculty and thus improves the quality of the debrief.

**Description**
The Description process involves taking the group through an “agreed description” of the scenario that has just finished. This should be done action-by-action, restricting the discussion to facts and avoiding emotion. The facilitator should start the debrief with a simple non-judgmental phrase, and then direct the conversation to those candidates not involved in the scenario to engage them in the process. This allows the scenario participants to rest and to reflect on their colleagues’ recollections of the events before giving their own accounts.

We argue that it is vital that the facilitator acknowledges comments about the perceived quality of the performance, but redirects away from performance evaluation at this stage; the focus should remain on creating a shared understanding of what actually occurred in the scenario. This ensures that scenario participants do not feel under attack, and that a safe learning environment is maintained.

Interestingly we do not use a venting, “How do you feel?” question initially as suggested by Rudolph et al. (2). We have not found this necessary and postulate that this may be cultural in that the model was developed in a UK rather than US setting.

At the end of the descriptive phase, the facilitators can clarify any outstanding clinical issues or technical questions. The diamond offers faculty the prompt “This scenario was designed to show... the recommended
management of which is...” This phrase allows the faculty to clarify the intentions of running the scenario, but accepts the limitations and emergent nature of simulation as a learning setting. Summarising the clinical management reinforces appropriate clinical knowledge, skills, protocol adherence or behaviour and addresses potential misconceptions without specifically focusing on participants’ performance (5). It also lessens the opportunity for collusion and draws a line under the clinical issues to prevent them from dominating the analysis phase.

Analysis
The analysis phase starts with an open question, such as “how did you feel?”, directed to the scenario participants. It is important that faculty allow enough time for the candidates to compose their answer, even if a few moments of silence seem uncomfortable. It may be necessary to follow up the response with “why?” or similar prompts, which can be asked multiple times until underlying feelings and motivations are revealed. This cycle can be reflected back to the group to compare and contrast perceptions and feelings, and to explore the nature of any potential dissonance expressed.

The analysis phase is where the facilitator structures the debrief around non-technical skills. Our faculty training recommends that only one skill is explored in each debrief to avoid cognitive overload for the learner. We encourage facilitators to focus on the skill the learners, not the faculty, feel was most relevant within the scenario. Faculty can then construct a framework within which these skills can be examined and developed, using
as a basis the shared and agreed experience of the scenario and the clinical experience of all participants.

Once these are aired, the facilitator should illustrate positive (and, we argue, only very carefully and with extreme caution negative) examples of the non-technical skill that is to be the focus. Guiding the conversation, the faculty can help to break this skill or behaviour down into specific actions that participants can use in their clinical environments. This is a facilitative process, during which the faculty member reflects and summarises the suggestions of the group, reframing them in non-technical language as appropriate.

The facilitator next moves through the transition with the phrase “So what we have talked about in this scenario is... What have we agreed we could do?” This reinforces the learning about the non-technical skills, ensuring a greater likelihood of remembering the detail in clinical practice settings.

**Application**

This phase encourages participants to consider how they may apply the knowledge in their own clinical practice. This aspect can be the most challenging for faculty as the learning needs to be drawn to a conclusion in a very focused way, without the introduction of alternative suggestions. Faculty should ask for specific summary points from the participants who made particular suggestions about non-technical skills and behaviours during the analysis phase. It is important to allow one or two participants to
contextualise this skill within their own working environment. This emphasis on applying the new skills to their own environments finishes up the debrief in a focused, yet personalised way.

**Implications**

Based on experiences in our centre, we argue that debriefing facilitators need both specific techniques and a clear structure to optimize learning during a debrief (10). We have developed the diamond to address this need. Currently there is considerable variation between the perceived ideal role of the debrief facilitator and what is actually executed during real debriefing sessions (7). We argue that a tool such as the diamond could help address this gap.

Further research is currently in process, to define the extent to which this model does indeed assist faculty in the delivery of post-simulation debrief, and to what extent it enhances the learning of participants. This includes research validating the use of the diamond in other settings; a more rigorous design-based inquiry exploring how the intentions of the diamond design are being reflected in actual debriefs, and in-depth interaction and conversational analysis of video recordings of diamond-based debriefs, which will demonstrate the extent to which debriefs using the diamond show clear evidence of learning and engagement with the simulation experience.

The feedback received from debriefs of over 6000 learners in our centre and other allied centres as well shows that the diamond encourages a
standardised approach to high-quality debriefing across courses and institutions, benefiting both participants and faculty. It facilitates debriefing in pairs, as the transition phases are a perfect point to switch faculty; it also allows junior faculty to conduct the relatively unproblematic description phase while more experienced faculty lead the later and more challenging phases.

As a cognitive scaffold for novice facilitators, we suggest that the diamond gives an easy and pedagogically sound structure to follow with specific prompts to use in the moment.

“So what happened? ... and then what happened next?”
Continue asking until confident that the details of the scenario have been raised by the candidates
“Let’s not judge our performance now, let’s just focus on what happened”

Transition
“This scenario was designed to show…”
“Let’s address technical & clinical questions. What is the protocol for …?”
“How do we normally deal with this clinical situation?”
“Everyone ok with that?”

“How did that make you feel?” To participants then group
“How?” Then use silence

“How did you / they do that exactly?”
“Why did you respond in that way?” or “Why did you take that action?”
“IT feels like … was an issue. Did it feel like that to you?”
“What I am hearing from you is … is that correct?”

“This is part of …” (identify the non-technical skill / human factor)
“We refer to that as a human factor or non-technical skill, which means …”

Transition
“So, what we’ve talked about in this scenario is …”
“What have we agreed we could do?”

“What other kinds of situations might you face that might be similar? How are they similar?”
“How might these skills we discussed play out in those situations?”
“What are you going to do differently in your practice tomorrow?”
Debrief Diamond: Underlying Principles

Description

- Reinforce a safe learning environment.
- Situate the debrief in the shared and meaningful activity that occurred.
- Keep the focus dispassionate—discuss what happened but avoid focusing on emotions.
- Listen for emotional responses but resist the temptation to discuss emotions.
- Make sure everyone shares the same understanding of what happened (share the mental model).

Analysis

- Transition into Analysis by clarifying any technical and clinical issues

- Spend most of your time in Analysis.
- Deconstruct behavior into specific actions, and explore what happened in detail.
- Ask about affective responses and validate them.
- Analyse and interpret the activity by applying appropriate frameworks or lenses (such as non-technical skills, or the clinical context surrounding the scenario).
- Keep the discussion positive, and avoid the temptation to focus on “strengths and weaknesses”.
- Reflect responses back, allowing participants to amend or augment.

Application

- Transition into Application by Reinforcing Learning

- Focus on moving from the specifics of the scenario to the more general world of practice.
- Break behaviours down into specific actions.
- Explore the other kinds of situations that these might apply to.
- Ask what participants will do differently in their practice.
